

Comparison of pre-treatment options for arsenic reduction in household water systems

Pretreatment to convert As(3) to As(5)		
Method	Advantages	Disadvantages
Chlorination	<p>Provides disinfection.</p> <p>Long history of effective use in public water systems.</p>	<p>Uses a hazardous chemical.</p> <p>Requires careful operation and maintenance.</p> <p>Chlorine may react with organic matter to form undesirable by-products.</p> <p>May cause a taste problem.</p> <p>Causes dissolved iron and manganese to precipitate, so filtration may be required.</p>
Manganese dioxide filter	<p>Requires no chemical use.</p> <p>Simple to operate.</p>	<p>Media can be expensive.</p> <p>Some vendors of household systems may not have expertise with the system.</p>
Pretreatment to remove iron		
Method	Advantages	Disadvantages
Water softener (ion exchange)	<p>Removes dissolved iron and manganese.</p> <p>Readily available; already used by many homeowners.</p> <p>Automated and simple to operate.</p>	<p>Not recommended for removing particulate iron or manganese.</p> <p>Produces salty brine that requires disposal.</p>
Oxidation/filtration	<p>Removes both dissolved and particulate iron and manganese.</p> <p>Removes some arsenic along with the iron.</p>	<p>Some systems require chlorine, which is a hazardous chemical.</p> <p>Produces waste water that requires disposal.</p>
